

JamBook Storage Management Options:

The main decision comes down to the offered complexity of the application and the options available to me. The two approaches can be:

- **Local Storage:** Storing data directly on the user's device.
 - Shared Preferences: Key-value pairs for simple user settings
 - Internal Storage: Files stored locally and accessible only by the JamBook app
 - Pros: Will serve the purpose of my app very well.
 - Cons: Not many actually. The obvious catch here is that I will need some form of web-based communication anyway to communicate with the API.
- **Cloud Storage:** Storing data on remote servers and enabling access from multiple devices.
 - Firebase: Has the positive of integrating very well with Android for media storage.
 - Amazon S3: Suitable for large-scale storage, but I really don't think my use-case will warrant the use of S3, or cloud storage in general.
 - Pros: It's scalable, but I'm not sure there are any other pros given my use-case.
 - Cons: Complex setup and potential outgoing costs.

I intend to keep user-data local, but there will have to be some form of online communication to fetch details from the API about current reservation status. I haven't yet figured out what that API looks like or if such an API exists.
